NEATHACK · DEVELOPER TOOL BUSINESS PLAN · 12 OCTOBER 2026

Parity Medic

neatHack business plan · developer tools · USD

Decision: validate a local-first verifier with paid, metered repair and evidence support. Do not build a broad hosted service or promise universal parity before proving demand and deployment safety.

Planning status: new hypothetical project, unrelated to Rajendra Institute of Medical Sciences. No paying customers, funding, commercial launch, customer time savings or market size are verified. No existing company records or integrations were used or changed. Every commercial figure below is a proposal or hypothetical planning input. The $5,000 starting cash is a hypothetical budget, not a verified bank balance.

Recommended route: five interviews → fresh evaluation → deployment gates → two paid pilots → CI evidence and reference drift.

Prepared by Ari in cfo.ai from the user-provided brief and labelled assumptions. This PDF is a static snapshot of generated planning output, not a provider invoice, customer validation or sponsor approval.

HYPOTHETICAL ECONOMICS · USD

Six cases. One honest cash view.

Full included usage: 20 individual / 100 team attempts; 80/20 mix; $0.05 per repair. Tax reserve: 20% of positive pre-tax cash profit. Account counts are not traction.

Accounts	Delivery	Monthly revenue	Full monthly cost	Burn / (surplus)	Runway months	Economic profit
0	Local	$0.00	$925.00	$925.00	5.41	($2,825.00)
0	Hosted	$0.00	$1,700.00	$1,700.00	2.94	($3,200.00)
100	Local	$3,500.00	$2,133.20	($1,366.80)	No finite limit	($533.20)
100	Hosted	$3,500.00	$3,041.20	($458.80)	No finite limit	($1,041.20)
500	Local	$17,500.00	$7,706.00	($9,794.00)	No finite limit	$7,894.00
500	Hosted	$17,500.00	$9,766.00	($7,734.00)	No finite limit	$6,234.00

Parentheses denote negative amounts. Runway uses the full hypothetical $5,000. No finite limit means no cash exhaustion under constant assumptions—not guaranteed survival. Economic profit also charges the unpaid portion of $2,500 founder compensation.

After the $1,500 validation reserve

Zero-account runway is 3.78 months local / 2.06 hosted on the remaining $3,500. Cash first turns negative at month-end in January 2027 locally or December 2026 hosted. No funding is modeled. Scale cases exclude one-time initial acquisition; see capital needs below.

Do not confuse steady-state economics with a funded growth plan

Target accounts	Indicative initial local acquisition	Indicative initial hosted acquisition
100	$4,000	$6,500
500	$20,000	$32,500

The hypothetical $5,000 does not establish a funded path to 100 or 500 accounts. CAC, conversion and churn are unvalidated.

COST BRIDGE · USD PER MONTH

Local delivery: every cost counted

Cost / outcome	0 accounts	100 accounts	500 accounts
Subscription revenue	$0.00	$3,500.00	$17,500.00
Inference	$0.00	$180.00	$900.00
Compute / storage	$0.00	$35.00	$175.00
Paid support	$0.00	$400.00	$2,000.00
Payment processing	$0.00	$131.50	$657.50
Fixed delivery infrastructure	$25.00	$25.00	$25.00
Delivery COGS subtotal	$25.00	$771.50	$3,757.50
Gross profit	($25.00)	$2,728.50	$13,742.50
Gross margin	—	77.96%	78.53%
Software / tools	$45.00	$45.00	$45.00
Legal / security contingency	$75.00	$75.00	$75.00
Administration / bookkeeping	$30.00	$30.00	$30.00
Founder cash stipend	$600.00	$600.00	$600.00
Growth experiments	$150.00	$150.00	$150.00
Churn replacement acquisition	$0.00	$120.00	$600.00
Hypothetical income-tax reserve	$0.00	$341.70	$2,448.50
Full recurring monthly cash cost	$925.00	$2,133.20	$7,706.00
Cash operating profit after reserve	($925.00)	$1,366.80	$9,794.00
Economic profit incl. unpaid founder time	($2,825.00)	($533.20)	$7,894.00

Rows labelled subtotal are not additional costs. Founder development compensation is operating expense; separately paid support is delivery cost. Legal/security allowance is a hypothetical reserve, not insurance coverage or an audit. The income-tax reserve is not a jurisdiction-specific liability.

COST BRIDGE · USD PER MONTH

Hosted delivery: every cost counted

Negative balances are visible funding gaps, not assumed borrowing. Annualized recurring revenue is not the same as an earned annual result.

Verification and provenance

Snapshot calculated in cfo.ai on 12 October 2026. Native engine results checked for all six cases, repair and pricing sensitivities and first/last projected cash. Independent arithmetic confirmed the revenue/cost/runway/cash bridge. Repair-cost driver test saved and restored. Canvas browser rendering passed in light and dark themes at 1200 px. Commercial assumptions, prototype evidence and contest eligibility are not independently verified.

1. Product, buyer and evidence

Parity Medic helps developers building agents and compatibility wrappers avoid silently changing an existing tool’s behavior. A developer supplies an adapter. The agent reads the original shipped implementation, tests revisions, and returns a measured result with supporting proof. The first reference is Bruno 4.2.1, limited to deterministic interpolation and JSON request preparation. It does not reconstruct arbitrary applications or send production requests.

The initial buyer is a small developer-tool team maintaining wrappers around stable open-source tools. The proposed job-to-be-done is less manual mismatch investigation, a reproducible contract, and evidence that a particular revision preserves supported behavior. Positioning: **maintained reference contracts and credible, reproducible verification evidence—not “an agent that can clone anything.”**

User-reported prototype evidence: one local repair improved 55/80 to 80/80, plus 80 independently chosen replay inputs. These reports were supplied in the planning brief; Ari did not inspect the repository or replay logs. Passing finite tests is not proof of universal parity, production safety or general customer impact. Do not combine the two sets into a claimed 160-test independent certification.

The successful repair reportedly used three model calls and 28,418 tokens. Neatlogs estimated $0.0117204 for that trace; it is not a provider invoice and omits unsuccessful debugging attempts and hosting. The model uses a deliberately higher hypothetical $0.05 per repair, with $0.25 and $1.00 stress cases. Those planning values are not measured average repair costs.

2. Offer and pricing hypothesis

- **Free local verifier:** supported deterministic checks and local proof output. Self-service documentation; no free cloud repair entitlement or unlimited human support. Users supply their own references and rights to use them.

- **Individual, proposed $19/month:** test 20 metered repair attempts/month, local-first use and evidence history. A failed or abandoned attempt can still incur model cost and should count against the quota.

- **Team, proposed $99/month per team account:** test 100 repair attempts/month, shared evidence, CI integration and private reference storage. Seats, retention and storage limits must be agreed during pilots; no implied unlimited seats or storage.

- The same prices are held constant across local and hosted alternatives to isolate delivery economics, not because price equivalence is validated. A fully local team edition stores private references and history under the customer’s control; the hosted alternative would provide managed storage only after security gates pass. Local distribution means no vendor-managed multi-tenant application or reference

store; optional model repair still requires an explicitly consented external-provider call. No on-device language model or offline repair capability is assumed. The vendor-paid inference allowance is hypothetical, not an implemented billing mechanism.

- **Provider-cost guardrail, proposed:** stop automatically at both the attempt quota and a provider-spend ceiling, initially $5 per individual and $20 per team per month. The financial base uses the attempt quotas only; it does NOT book an unvalidated saving from these extra dollar limits. At $1/attempt, those ceilings would permit at most 5 and 20 attempts respectively. Explain that reduction before purchase; never silently reduce the promised entitlement.

- **Overages, interview proposal:** opt-in, prepaid at 1.5× estimated provider cost, with a disclosed minimum charge if necessary. No overage revenue is modeled. User consent, cost estimates and an explicit stop are mandatory. Reprice or reduce included usage if high-cost repairs persist.

Repair-count caps alone are insufficient: at $1 per repair, 20 individual attempts consume $20 of inference against a $19 price, and 100 team attempts consume $100 against $99—before compute, payments or support. At an uncapped 100 repairs/customer/month, inference alone is $5, $25 or $100/customer. The individual offer therefore cannot promise 100 included repairs under the expensive case.

3. Hypothetical commercial and cost assumptions

The model treats a customer as one paid account, not a seat. Mix is 80% individual / 20% team: 100 accounts means 80 individual and 20 team; 500 means 400 and 100. Weighted revenue is $35/account/month. At full included utilization, the weighted repair allowance is 36 attempts/account/month. No customers are assumed to exist today; the 100 and 500 cases are illustrative steady states, not acquisition forecasts or commitments.

Monthly churn is assumed at 3%, evenly across offers. Replacing churn keeps account counts constant: 3 replacements/month at 100 accounts; 15 at 500. Hypothetical replacement CAC is $40 local and $65 hosted. Additional acquisition experiments cost $150/month local and $300 hosted. These experiment budgets produce **no assumed new customers**. Initial customer acquisition is not magically free: acquiring 100 accounts at those CACs would cost $4,000 / $6,500; acquiring 500 would cost $20,000 / $32,500, before churn replacement and experimental spend. These are indicative initial-acquisition needs, not charges in the steady-state monthly tables. A $5,000 budget does not demonstrate a funded route to either scale case. Referrals, community distribution and founder selling must be validated rather than booked as free growth.

Local variable delivery inputs: compute/storage $0.25 individual / $0.75 team; support 0.10 / 0.40 hours per account per month at $25/hour. Weighted support is $4 and compute/storage $0.35/account. Local customer devices run the verifier; the service’s $25/month fixed delivery allowance is for licensing/update/evidence distribution, not private-reference cloud execution.

Hosted variable delivery inputs: compute/storage $0.75 individual / $3.00 team; support 0.15 / 0.60 hours at $25/hour. Weighted support is $6 and compute/storage $1.20/account. Add $150/month fixed hosting/observability/job infrastructure. Hosting allowances are hypothetical and do not establish that the required architecture exists.

Both alternatives: payment processing assumed 2.9% of subscription receipts plus $0.30/account/month. Baseline inference is $1.80/account at full weighted allowance. Support is separately costed capacity, not free founder labor; at 500 accounts, it represents 80 hours/month local or 120 hours hosted.

Monthly local overhead: software/tooling $45; legal/security/insurance contingency reserve $75; administration/bookkeeping $30; founder cash stipend $600; growth experiments $150. Including fixed delivery gives $925/month before account-linked costs.

Monthly hosted overhead: software/tooling $60; legal/security/insurance contingency reserve $150; administration/bookkeeping $40; founder cash stipend $1,000; growth experiments $300. Including fixed delivery gives $1,700/month before account-linked costs.

Founder full-time development, reference maintenance and selling are hypothetically valued at $2,500/month, not asserted as a market salary. The cash stipend is included in cash cost; the remaining unpaid value is disclosed through economic profit, subtracting another $1,900 local or $1,500 hosted. This prevents cash surplus from being described as full labor-cost profitability.

A hypothetical **20% reserve on positive pre-tax cash operating profit** is included in cash costs, separately from the legal/security contingency. This is a prudence assumption, not a jurisdiction-specific tax calculation or an incurred liability. No loss tax refunds, financing, debt service, distributions, capex, paid seats beyond these accounts, FX or annual-prepayment benefit are assumed. Prices are USD before any applicable sales taxes, which are assumed pass-through. Actual entity, tax, insurance, licensing and employment obligations must be established before selling. Cost categories are fully itemized for this planning scope; amounts are not vendor quotes and do not guarantee real deployment costs.

4. Revenue, margins and cash interpretation

The accompanying native tables and Canvas compare 0, 100 and 500 accounts, both delivery alternatives, three repair-cost assumptions and ±25% pricing. Lower-price offers are $14.25 / $74.25; higher-price offers are $23.75 / $123.75. Pricing sensitivity holds mix, churn, utilization and account count constant; it measures arithmetic, not demand elasticity.

Baseline recurring revenue is $0, $3,500 or $17,500/month, and annualized recurring revenue run rate is 12× monthly revenue—not an earned annual forecast. Full monthly costs include inference, compute/storage, paid support, processing, fixed infrastructure, tooling, contingencies, administration, founder stipend, replacement acquisition, experiments and the hypothetical profit-tax reserve.

Gross profit deducts inference, compute/storage, paid support, processing and fixed delivery infrastructure. It excludes selling, administration, founder product-development compensation, contingency and tax reserve. It is **not inference-only margin**. At zero revenue gross margin is undefined, not 0% or 100%. Monthly cost totals and profit are more decision-useful than that undefined ratio.

Net monthly burn = full recurring monthly cash costs − subscription cash receipts. Positive burn consumes cash; negative burn is a cash surplus. Cash runway = $5,000 / positive net monthly burn. Non-burning and profitable cases have **no finite cash-runway limit under those constant assumptions**; this is not a guarantee of survival or a claim of infinite demand.

The base cash break-even levels are 36 local or 75 hosted accounts, under the assumed mix and full quota use. At 100 accounts, both show cash surplus but negative economic profit after unpaid founder time. This is a viable validation experiment, not yet proof of a fully compensated business.

The 12-month projection runs October 2026–September 2027 with constant case economics and no funding. It spends the $1,500 validation budget at inception, leaving $3,500 for operations. The companion main runway numbers deliberately use the requested full $5,000; the post-validation runway rows use $3,500 so the one-time cost is not hidden or double-counted. At zero accounts that leaves 3.78 months local or 2.06 months hosted. Monthly end balances first go negative in January 2027 locally or December 2026 hosted. These are hypothetical start-date conventions, not real insolvency forecasts.

The repair sensitivity compares capped 36 weighted repairs against 100 repairs/account with no overage revenue. It changes inference alone, leaving support, retries and infrastructure unchanged; correlated support or failure-cost increases would make the expensive cases worse. At 100 accounts and $0.25/repair, hosted capped usage burns $146.50/month; uncapped usage burns $611.50 local or $1,746.50 hosted. At $1/repair, even capped usage burns cash in both alternatives. This is why usage limits and provider-cost guardrails matter more than the headline prototype trace cost.

5. Validation milestones and $1,500 budget

All dates are hypothetical relative targets from kickoff. Spending is gated; the projection conservatively reserves the entire validation amount immediately. Go/no-go thresholds below are proposed decision rules, not observed results.

Weeks 1–2 · wrapper interviews · $150. Interview five developers who maintain wrappers. Obtain an actual historical mismatch, baseline time-to-diagnose, security requirements, and a named buyer. Proceed only if at least three describe recurring supported-scope pain and at least two agree to test their own cases. Record rejections as well as interest. Deliver anonymized interview notes and a pricing/usage-limit objection log.

Weeks 2–3 · second contract and provider · $350. Add a second independently verified reference contract and a second model provider. Choose the reference only after source-access and license review; no second tool or vendor is claimed here. Measure correct refusals as well as repairs. Pass only when scope and version are explicit, reference evidence is reproducible, and both providers can complete a bounded job or fail safely under an agreed cost ceiling.

Weeks 3–4 · preregistered evaluation · $300. Before running, freeze a protocol with 120 fresh cases: 60 supported valid, 30 supported malformed/edge cases with declared outcomes, and 30 unsupported cases. Keep development fixtures separate; log all attempts, failures, latency, repair time and provider cost. Proposed pilot gates: at least 95% correct supported outcomes; no false acceptance in the 30 unsupported cases; median inference ≤$0.05 and p95 ≤$0.25 per attempted repair; a p95 completion-time target agreed with interview participants before the run. Report denominators, uncertainty and failures; zero observed false acceptances in a small sample does not establish zero true risk. If gates fail, narrow scope or change quotas and rerun a fresh holdout.

Weeks 4–5 · security and recovery · $400. Review payload boundaries, local versus remote execution, licensing, tenant isolation, secrets, durable job leases, retry/idempotency, recovery after worker loss, storage retention/deletion and auditable provider consent. Proposed hosted gate: deny cross-tenant access in designed tests; redact secret fixtures; demonstrate deletion and bounded retries; recover interrupted work without duplicate side effects or unbounded charges. A $400 review allowance is a bounded validation step, not an audit or production-readiness certification. If that cannot cover the work, keep pilots local and re-budget.

Weeks 5–6 · limited pilot · $200. Offer paid access only after boundaries and recovery meet the pilot’s deployment needs. Seek two independent paying pilot accounts with explicit quota, consent, unsupported-scope terms and stop controls. Measure ≥30% median diagnosis-time reduction on paired historical mismatches against each developer’s actual baseline; separately log setup burden, reruns, support minutes and renew/reject decisions. This is a validation target, not existing traction. Do not record future pilot revenue before someone pays.

Weeks 6–8 · CI exports and version drift · $100. Produce versioned proof/evidence exports, provenance, reference fingerprints and a drift warning when Bruno or another supported reference changes. Gate expansion on repeat usage and a customer’s real CI workflow; a broad marketplace of reconstructed apps is deliberately out of scope.

If interviews fail, stop after the first tranche and preserve unspent budget. Do not spend the whole $5,000 building a platform before validating a costly, recurring problem.

6. Risk register and mitigations

- **Finite tests and overfitting · existential product risk.** Frozen independent holdouts, versioned supported scope, negative tests, refusal metrics and reproducible proof. Residual: accepted repairs can still fail outside the finite contract. Never market universal parity.

- **Reference source access and licensing · launch blocker.** Per-reference license/source review; record permitted versions and use. Exclude references whose rights or access cannot be established; no right to redistribute original source is assumed.

- **Provider behavior, pricing and reasoning mode · margin/reliability risk.** A second provider, provider/version logs, bounded calls/tokens/retries, spend stops and re-evaluation after configuration changes. User reports reasoning mode exhausted the prototype budget until configured correctly; the successful trace excludes those unsuccessful attempts.

- **Secrets and private references · high impact.** Local by default, explicit consent before sending data, strict retention/deletion and secret-redaction tests. Hosted access remains gated behind tenant isolation and recovery. Private reference storage is not a promise of audited security.

- **Popular coding agents incorporate similar features · competitive risk.** Win on maintained contracts, credible evidence, CI outputs and version drift—not generic repair chat. No external competitive research or exclusivity is claimed.

- **Demand and time savings unvalidated · commercial risk.** Five problem interviews, paired time-to-diagnose tests, real paid pilots and renewal decisions before scale spend. Proposed prices, mix, CAC and churn may all be wrong.

- **Support and infrastructure underestimate · capacity risk.** Log support per account, storage, retention and retry burden; reprice when p95 cost or support breaks the assumed budget. At 500 accounts, paid support is a real operating function, not a hobby.

- **Capital and income gap · founder risk.** Only hypothetical starting cash exists. No funding is modeled. Initial acquisition and adequate founder compensation need a route to financing from receipts, reduced scope or explicitly hypothetical additional funding—not invented traction.

7. Launch and financing strategy

Start fully local: free verifier, bounded paid repairs, versioned evidence and CI artifacts. Founder-led outreach to the five interview participants and referrals is a test channel, not validated distribution. Keep the $150 local experiment budget small until cost-per-converted-account and diagnosis-time reduction are measured. Do not assign a TAM or projected conversion rate without evidence.

Hosted teams are a conditional second delivery option, not the hackathon prototype’s existing architecture. Build only the minimum tenant boundaries, durable jobs, provider consent, retention and recovery required by an agreed pilot. The extra fixed and variable costs are modeled separately; the two alternatives are mutually exclusive and must never be added together as one business.

Recommend a gated $1,500 validation reserve, local recurring operations and no hypothetical raise in the base case. The 100- and 500-account cases demonstrate what the economics could look like at scale; they do not demonstrate that the company can acquire those

accounts within the starting budget. Before seeking money, preserve fresh evaluation results, paid-pilot consent, measured costs and retention evidence. Funding need depends on real growth spending and founder compensation; it is not verified here.

8. Method, checks and actual provenance

Ari generated this plan inside cfo.ai on 12 October 2026 from the user’s prepared Parity Medic brief and explicitly hypothetical assumptions. No internet research, accounting feed, CRM, HRIS, provider invoice, repository or external company data was used. The workspace name was not used as company identity and was not changed. Account setup was reported complete by the user; it was not independently inspected.

The native model contains editable assumptions, a customer mix, itemized delivery/operating costs, tier costs, scenario comparisons, repair and price sensitivities, an itemized validation budget, a hypothetical tax reserve and 12-month cash projections. Main is the 0-account case; the two named Parity Medic scenarios override only the account input to 100 and 500. A Canvas simulator provides read-only previews; previews do not change saved financial inputs.

Checks include saved engine calculations for all six customer/delivery combinations; independent arithmetic of revenue, cost bridge, conditional runway and first/last projected cash; and a saved repair-cost driver test in the 100-account case, followed by restoration of $0.05. Repair/price sensitivity and tier rows were inspected from the native engine. Browser validation checks Canvas rendering at the tested width, not correctness of commercial assumptions or a click’s behavior. Static exports preserve the generated report and calculated snapshot; the editable workbook carries any formula-export limitations on its Export notes sheet.

This is actual cfo.ai-generated planning output, not evidence of product demand or prototype correctness. The saved page and downloadable artifacts preserve that provenance for the demo. Whether this satisfies any neatHack sponsor rule depends on the rule and judges; no unprovided contest requirement or sponsor approval is asserted.
